HYDROLOGICAL MEMORANDUM No. 22

RAINFALL OVER THE AREAS OF THE THAMES AND LEE CONSERVANCIES, LONDON, AND THE BRENT, THE WANDLE AND THE BOURNE VALLEYS, 1916–1950

1. Rainfall, 1916–1950

1.1. *Introduction.* The estimation of standard-period averages for the months, or for the year, is carried out in three stages: the selection of sound, homogeneous records complete for the 35 years, 1916–1950, which provide arithmetic means of monthly and annual rainfall, the basic values for all other work; the estimation of standard-period, annual averages for short-period stations; the estimation of standard-period, monthly averages for stations in the second group, where these are needed for special purposes.

A detailed account of the methods developed and used in the Meteorological Office (Met O 8) to estimate standard-period averages from short-period records is given in Hydrological Memorandum No. 5.

It is possible to process the data in a number of ways but the maps and tables are presented here in the simplest, most precise forms in order to be of use to a wide range of enquirers.

1.2. *The Primary Survey,* for Great Britain and Northern Ireland, of stations with complete records during 1916–1950 included some cases where the site had been changed to one with a better exposure, and observations from both sites had been recorded for a few years. Attempts were made to amend the earlier readings by comparison of the data during a period of overlap, in order to have a set of values from 1916 to the date of the change, which would be representative of the later, and better, record. But since the earlier exposures were usually unsatisfactory (being over-exposed or over-sheltered), the results were mostly erratic and the amended sets of values were not homogeneous. In a few cases, small breaks in a long record were completed by using estimated values, based on a nearby station, with or without the use of a modifying fact factor.

Of the many records examined, monthly and annual averages were accepted for 94 stations, 44 for the Thames, 22 for the Lee and 28 for London. The accepted values (in inches), together with the proportions (per cent) of each monthly average to the annual average, are given in Table I, together with the altitude and the National Grid reference for each station. Most of these averages were included in HMSO publication, Met. O. 635, *Averages of Rainfall for Great Britain and Northern Ireland, 1916–1950,* some were omitted because other stations were so near.

The percentage proportion of monthly averages to the annual averages for the long-period stations were used to draw a series of twelve monthly maps from which it is possible to estimate the percentage of average annual rainfall, for any place, for each month of the year. These maps are shown as Figure I. Values estimated for a few points between the isopercental lines have been added to give a clearer indication of the variations from place to place. The points chosen are not necessarily the same for each map.

1.3. *The Secondary Survey* of short-period stations was undertaken next, using records up to the time of the survey, usually into the late 1950s. Long-period stations, whose averages had been rejected from the Primary Survey because the record was not homogeneous, were examined again and averages were estimated for the later (and usually improved) part of the series of observations. Averages based on data for less than 5 years were not usually accepted for publication. A list of the accepted averages, for the short-period stations, is given in Table II, together with the altitude and National Grid reference for each. The stations are listed in an order based on natural drainage areas which will be used for the first time in *British Rainfall 1961.*

These averages, together with the long-period averages listed in Table I, were plotted on Ordnance Survey maps (scale 4 miles to the inch) and used to draw the lines of average annual rainfall, 1916–1950. The map is shown as Figure 2. The Secondary Survey is frequently revised for special areas using the most up-to-date observations for relatively new stations and the map is subject to revision from time to time. The redrawing of the isohyets usually results in greater detail and perhaps a clearer definition of a wet area as more and more observations become available from improved River Board networks of rain-gauges. Drastic changes are not expected. In Tables I, II and III, with a few exceptions, the average quoted are for records still being maintained in 1963.

1.4. *Monthly Averages* for a further group of stations were next estimated for use in the *Monthly Weather Report* and for enquiries. For this purpose some stations were chosen from those listed in Table II to supplement those listed in Table I. To find the monthly averages, the monthly proportions (per cent of annual average) were chosen from the equipercental maps (see Figure 1) so that the total for the twelve months was 100. These monthly percentages were then used to apportion the annual average (in inches) amongst the months. The results are given in Table III.

1.5. *Daily Rainfall, 1916–1950.* Four of the initial 94 records which were accepted for the Primary Survey (1.2.) were analysed further and to these we have added two more just outside the area, Cheltenham and Andover. These records had regular daily entries, for the 24-hour period 0900 to 0900 for each of the 35 years, 1916–1950. Table IVa gives, for each of the stations, the 35-year totals for each day of the year (in inches). Table IVb gives 1/35 of all possible totals from .17 inch to 24.67 inches, thus providing a reduction table for the values in IVa to give average daily falls from 'trace' to .70 inch. For 29 February the reduction factor is of course 1/9.

These daily averages can be regrouped as 5-day means, 7-day means, consecutive or sliding means, or in whatever form suits a specific requirement.

2. Frequencies of Daily Rainfall, 1916–1950

The same set of daily values used for Table IVa were regrouped to give frequency tables with intervals of .01 inch. These have been rearranged in Table V, to give accumulated frequencies with intervals of .10 inch up to 2.50 inches and a wider grouping above this.

3. Extremes of Rainfall

The records for the 35-year period, 1916–1950, for the stations used in Tables IV and V were also used to find maximum and minimum values for the year and for each month and also maximum daily values for each month. These maxima and minima are given in Table VI and Table VII. Additional extremes are given in these tables to cover the 50-year period, 1911–1960. Monthly extremes (Table VI) are given for four additional stations, Reigate, Marlborough, Cirencester and South Farnborough.

Appendix I

Intense Falls. Falls of 2 hours or less, which have been recorded in *British Rainfall* and rank as 'noteworthy', 'remarkable' or 'very rare', are listed in Appendix I.

(H. ROWSELL)

Meteorological Office, Met O 8
Bracknell, Berkshire

TABLE I Monthly and Annual Averages of Rainfall (in inches), 1916-1950. Thames and Lee Conservancy areas and London, including the Brent, Wandle and Bourne Valleys.
